The Polychrony Tool set

Signal

- to validate a design at different levels,
- to refine descriptions in a top-down approach,
- to abstract properties needed for black-box composition,
- to assemble predefined components (bottom-up with COTS).

Signal is based on synchronized data-flow (flows + synchronization): a process is a set of equations on elementary flows describing both data and control, the variables of the system are signals. A signal is a sequence of values which has a clock associated with; this clock specifies the instants at which the values are available.

The Signal formal model provides the capability to describe systems with several clocks (polychronous systems) as relational specifications. Relations are useful as partial specifications and as specifications of non-deterministic devices (for instance a non-deterministic bus) or external processes (for instance an unsafe car driver).

Using Signal allows to specify an application, to design an architecture, to refine detailed components down to RTOS or hardware description. The Signal model supports a design methodology which goes from specification to implementation, from abstraction to concretization, from synchrony to asynchrony.

The principal application areas for the Signal language are that of embedded, real-time, critical systems. Typical domains include:

- Process control,
- Signal processing systems,
- Avionics,
- Automotive control,
- Vehicle control systems,
- Nuclear power control systems,
- Defense systems,
- Radar systems...

It constitutes a development environment for critical systems, from abstract specification until deployment on distributed systems. It relies on the application of formal methods, allowed by the representation of a system, at the different steps of its development, in the Signal polychronous semantic model.

For more information concerning the INRIA Polychrony environment, consult the ESPRESSO team website:

Topcased Modeling

Navigator view

Outline view

Editor view
Diagram. For an edited Topcased Diagram, the left of this view is dedicated to the palette of the graphical object that can be dragged/dropped into the Diagram part. One can also drag an element from the Outline view to the Diagram part, and if there is a graphical element which corresponds to this model object for the displayed diagram, it will be added.

4. The Property view displays the lists of properties of the model object selected in the Outline view and/or in the Diagram view. Some of the properties can be modified and others are just read-only information.

Remark:
- Delete From Diagram:
- Delete From Model (Shift+Del): delete the graphical and the model object elements.
Creation of a new project

New -> Project ...

Next >

Finish
Thus, you will obtain a new project, which contains only a .project file.
The reflexive editor plug-in

Creation of a new .sme model file

New-> Other...  Polychrony-> SME Model.

Once you have selected the **SME Model**, the SME wizard is opened. Thus, you have to choose the name of the diagram, select **Next>** and then select the kind of the root for the model file.

There are two kinds of root model element:

- **Model Declaration**: it corresponds to a SIGNAL component (i.e. process)
- **Module**: it corresponds to a library of components, types, and constants.

Once, you have chosen the root model, you have only to add new model objects. To do so, right-click on the node on which you want to add a child, and select the **New Child** menu. It displays the list of all possible model elements that can be added for the current selected element. If this option does not exist for a node, it means that there is no possible child for this node.

8
Array Enumeration

It corresponds to the Signal operator for defining an array by
the ordered list of its elements.

Children:
- Input Port: this operator is a multiple inputs operator, this means that you can add as
  many Input Ports as Signal Expressions you need (at least 2) to connect. The ports
  are ordered.

Basic
- Name: the name of the operator. It is used to identify it, so it is better if it has a
  unique name.

Array Product

It corresponds to the Signal operator for a matrix product.
The operands must have a basic type which is a numeric type.

Children:
- Input Port: this operator is a multiple inputs operator, this means that you can add as
  many Input Ports as Signal Expressions you need (at least 2) to connect. The ports
  are ordered.

Basic
- Name: the name of the operator. It is used to identify it, so it is better if it has a
  unique name.

Array Recovery

It corresponds to the Signal operator for defining a recovery
default value when accessing to an array out of its bounds.

Children:
- Two Input Ports already created. The first one takes an array expression and the
  second one takes a recovery expression, which is used when the array expression try
  to access out of the bounds of the array.

Basic
- Name: the name of the operator. It is used to identify it, so it is better if it has a
  unique name.

Array Restructuration

It allows to define partially an array, by defining some indices-
defined coordinate points of this array. Non defined values are
any values of correct type.

Children:
- Two Input Ports already created. The first one takes an expression corresponding to
  the index(es) of the array at which the expression indicated by the second port is set.

Basic
- Name: the name of the operator. It is used to identify it, so it is better if it has a
  unique name.

Assertion

It corresponds to a process with no output which specifies that a
Boolean expression must have the value true each time it is
present.

Children: none

true
**Basic**

- **Expression:** the boolean expression to check in a textual form. If a Condition references this Assertion, the boolean expression at the source of this Condition will be the expression to check.

- **Name:** the name of the operator. It is used to identify it, so it is better if it has a unique name.

**Assertion Clock**

- Constraint Operator

  It corresponds to the different kind of clock constraint operator in a context of an assertion. To use this operator, connect the different expressions to it with Clock Relation model object.

**Children:** none

**Basic**

- **Name:** the name of the operator. It is used to identify it, so it is better if it has a unique name.

  - **Operator:** this attribute is of enumerated type whose values are `Synchronized` (clocks are equal), `Excluded` (specifies the mutual exclusion of the expression clocks), and `Identity` (specifies the equality of values and clocks of the expressions). By default, the value of this attribute is `Synchronized`.

**Assertion Clock Speed**

- Operator

  It corresponds to a clock constraint operator which constraints the speed of a Clocked Expression to be greater (or smaller) than the speed of another Clock Expression. This means that the first Clocked Expression is more (or less) frequently present than the second one. This operator is used in the context of an assertion.

  - **Children:**
    - **Input Port:** this operator is a multiple inputs operator, this means that you can add as many Input Ports as Signal Expressions you need (at least 2) to connect. The ports are ordered.

**Automaton**

- It corresponds to the definition of a mode automaton.

  - **Children:**
    - The sub states (And State, Automaton, and/or State) indicate the different execution mode in which the Automaton can be. At each instant, the Automaton can execute at most one mode.
    - **History:** connecting a transition to the history of an Automaton means that you re-execute the last mode of this Automaton.
    - **The shared Local signals.**
    - **The transitions (Weak Transitions, or Strong Transitions) of the Automaton define the means to go from one state to another one when their guard is true.**
Comment: the COMMENT pragma attached to this identifier.

The Initial State indicates the initial state of this automaton. All possible states are listed in the combo box.

Name: the name of the Automaton which is used as its identifier. It has to be unique inside its container. It is even better to name it uniquely inside the file.

Basic Iterate

It corresponds to a C- for loop: for(i=0; i <= N; i++). It is a particular case of the Iterate block.

Children:

- Iteration Init: this model object already created is used to specify, if any, how to initialize the iteration. When you try to delete this object, it is automatically rebuilt, but it will be empty.
- Iterator: it is a constant expression that is used to iterate among all elements contained in the Basic Iterate block. It corresponds to the i parameter in a C- for loop for(i=0; i <= N; i++). The iterator is automatically added to the Basic Iterate block. When you try to delete this object, it is automatically rebuilt with unset attribute.
- Any of the children that can be in a process: it means all model objects except the following list: And State, Input, Model Declaration, Output, Parameter,Pragma, State, Strong Transition, and Weak Transition.

Basic

- Comment: the COMMENT pragma attached to this identifier.
- Iterator Name is used to get/set the name of the iterator used by the Basic Iterate Block. This attribute is a shortcut. Obviously, one can change the name of the iterator directly in the Iterator element.
- Name: the name of the Iterate which is used as its identifier. It has to be unique inside its container. It is even better to name it uniquely inside the file.
- Upper Bound represents the upper bounds of the iteration (the N parameter of the C- for loop). It has to be an integer expression: integer value, expression using signals...

Boolean Expression

It corresponds to a complete boolean expression. It was added to the meta-model to avoid a long description of a complete boolean expression.

Children: none

Basic

- Expression: the boolean expression in a textual form.
- Name: the name of the operator. It is used to identify it, so it is better if it has a unique name.

Cartesian Product

The Cartesian product is used mainly to define jointly indexes, to be used in Iterate model object. Intuitively, the sequence of iteration is represented by the first dimension of the indexes (which are vectors).

Children:

- Input Port: this operator is a multiple inputs operator, this means that you can add as many Input Ports as you need (at least 2). The ports are ordered.
- Output Port: this operator has also as many Output Ports as Input Ports (at least 2)
### Case

- **ClosedInterval**
- **LeftHalfOpenInterval**
- **RightHalfOpenInterval**

Intervals are not fully implemented by the compiler yet.

### Clock Constraint Operator

- **ElseCase**

Intervals are not fully implemented by the compiler yet.
● Operator: this attribute is of enumerated type whose values are Synchronized (clocks are equal), Excluded (specifies the mutual exclusion of the expression clocks), and Identity (specifies the equality of values and clocks of the expressions). By default, the value of this attribute is Synchronized.

Clock Relation
It corresponds to a clock relation between two clocked expressions. A Clocked Expression is either a signal (Input, Output, Local, Signal Ref, Input Instance, Output Instance), or a Sub Process, or an Iterate, or a Model Instance, or an Automaton, or any clock operator (Clock Constraint Operator, Clock Relation Operator, Clock Speed Operator).

Basic
● Name: the name of the model object. It is used to identify it, so it is better if it has a unique name.

Source-Target
● Dst: the target of a Clock Relation is a Clocked Expression.
● Dst Field: if the target is a Signal using a Tuple Type or an array type, this attribute is the way to access to the signal field.
● Src: the source of a Clock Relation is also a Clocked Expression.
● Src Field: if the source is a Signal using a Tuple Type or an array type, this attribute is the way to access to the signal field.

Clock Relation Operator
It corresponds to the set operators for clocked expressions.

Children:
● Input Port: this operator is a multiple inputs operator, this means that you can add as many Input Ports as Signal Expressions you need (at least 2) to connect. The ports are ordered.

Basic
● Name: the name of the operator. It is used to identify it, so it is better if it has a unique name.
● Operator: this attribute is of enumerated type whose values are Union, Intersection, and Complementary. By default, the value of this attribute is Union.

Clock Speed Operator
It corresponds to a clock constraint operator which constraints the speed of a Clocked Expression to be greater (or smaller) than the speed of another Clock Expression. This means that the first Clocked Expression is more (or less) frequently present that the second one.

Children:
● Input Port: this operator is a multiple inputs operator, this means that you can add as many Input Ports as Signal Expressions you need (at least 2) to connect. The ports are ordered.
Comparison Operator

It corresponds to the Boolean relations of equality, difference, and strict and non strict greater and lower relations. The value of both expression must be comparable.

Basic

- **Name**: the name of the operator. It is used to identify it, so it is better if it has a unique name.

- **Operator**: this attribute is of enumerated type whose values are Equal, Not Equal, Greater, Greater Or Equal, Smaller, Smaller Or Equal, Equal Any, and Smaller Or Equal Any. By default, the value of this attribute is Equal. The difference between Equal and Equal Any, is that if the first one is applied on two vectors, the result is a vector of Booleans, whereas the second one returns a single Boolean value (same distinction between Smaller Or Equal and Smaller Or Equal Any).

Complex Operator

It corresponds to the operator for building complex number.

Basic

- **Name**: The name of the operator. It is used to identify it, so it is better if it has a unique name.

Concatenation

It corresponds to the concatenation operation, which allows to concatenate arrays along to their first dimension.

Basic

- **Name**: the name of the operator. It is used to identify it, so it is better if it has a unique name.

Condition

It corresponds to the expression of a condition for some specific Conditioned Expression: the Assertion, the Cell, the Dependence Operator, the Extraction, or the If Then Else.

Basic

- **Condition Kind**: this attribute is of enumerated type whose values are Present, True, False, and Error.
False       True       False       Present       Present

...
unique inside its container. It is even better to name it uniquely inside the file.

- **Type**: it corresponds to one of the Intrinsic Primitive Type or to one of the type declared. To access to a type declared in the file, the Constant Value has to be in the scope of this declaration.

- **Value**: indicates the value of the constant. If the constant is an array, specify one value (of the first dimension) per line.

- **Visibility**: indicates the visibility (public or private) if the Constant Value is declared inside a Module. If it is declared in a Model Declaration, this information is useless.

**Counter**

- It allows the numbering of the occurrences of a signal.

**Children**:

- **Two Input Ports already created. The first one has to be connected to the Signal Expression, which has to be numbered, and the second to a reseting event (if Counter Kind is After or From) or to a constant integer expression (if Counter Kind is Count).**

**Basic**

- **Counter Kind**: this attribute is of enumerated type whose values are `After`, `From`, and `Count`. By default, the value of this attribute is `After`.
  - `After` means that it counts the number of occurrences of the first Signal Expression since the last occurrence of the reseting event.
  - `From` works as `After`, but if the Signal Expression and the reseting event are simultaneous, it is counted by `From` (not by `After`).
  - `Count` means that it counts the number of occurrences of the Signal Expression modulo the number of the second expression.

- **Name**: the name of the operator. It is used to identify it, so it is better if it has a unique name.

**Dataflow Connection**

- It corresponds to the Signal definition (or partial definition). It constitutes the main link between signal expressions.

**Children**: none

**Basic**

- **Name**: the name of the model object. It is used to identify it, so it is better if it has a unique name.

**Expert**

- **Cast Type**: it corresponds to the casting type for the source expression. The type is one of the Intrinsic Primitive Type.

- **Is Default Value**: if the destination is a shared Local signal or a state variable, this attribute indicates if the source expression constitutes the default value of the partial definition.

- **Use Last Iteration Value**: indicates if the source expression used is those computed during the last iteration (this attribute is only used inside an Iterate model).

- **Use Src Clock**: indicates if the Dataflow Connection uses the clock of the source or its value.

**Source-Target**

- **Dst**: the target of a Dataflow Connection is a Signal (Input Instance, Local, Output, Signal Ref) or an Input Port of an operator (except for Clock Relation Operator).

- **Dst Field**: if the target is a Signal using a Tuple Type or an array type, this attribute is the way to access to the signal field.
Src: the source of a Dataflow Connection is a Signal Expression: operators (except Clock Constraint Operator, Clock Relation Operator, Clock Speed Operator, and Dependence Operator), Signals, or Output Port.

Src Field: if the source is a Signal using a Tuple Type or an array type, this attribute is the way to access to the signal field.

Delay corresponds to the delay operator which returns the \( \text{Nb Instants}^{-\text{th}} \) previous value of a Signal Expression, except for its first \( \text{Nb Instants}^{-\text{th}} \) execution where it uses the initial value.

Children:
- One Input Port already created to connect the Signal Expression to delay.

Basic

- Initial Value initialize the value for the \( \text{Nb Instants}^{-\text{th}} \) first execution of the operators.
- Name: the name of the operator. It is used to identify it, so it is better if it has a unique name.
- \( \text{Nb Instants} \): the size of the delay. You can specify an integer positive value or the name of a constant value.

Dependence

It corresponds to an explicit specification of dependences between Identifiers (Signals, Model Instance, Sub Process, or Iterate) model objects. When the source (or target) is a Model Instance, a Sub Process, or an Iterate model object, it means that all Signals defined in these structure enter in the Dependence relation.

Children: none

Basic

- Name: the name of the model object. It is used to identify it, so it is better if it has a unique name.
- Source-Target
- Dst: the target of a Dependence is an Identifier model object.
- Dst Field: if the source is a Signal using a Tuple Type or an array type, this attribute is the way to access to the signal field.
- Src: the source of a Dependence is an Identifier model object.
- Src Field: if the source is a Signal using a Tuple Type or an array type, this attribute is the way to access to the signal field.

Dependence Operator

It has been introduced to represent conditional Dependences. Thus, one can connect the target of a Condition to this operator, and the source or target of several Dependences.

Children: none

Basic

- Name: the name of the operator. It is used to identify it, so it is better if it has a unique name.
Enumeration Type

It corresponds to the type declaration of an enumeration. To access to the value of an enumerated type, prefix the value by a '#' character.

Children: none

Basic

- Array Dimensions indicates the dimensions of the Enumeration Type, if it is an array type. If it is a multi-dimensional array, specify one dimension per line. A dimension is a constant expression: Constant Value, Parameter, an integer positive number...

- Comment: the COMMENT pragma attached to this identifier.

- Enum Values indicates the values of the enumeration. Put one value per line.

- Name: the name of the Enumeration Type, which is used as its identifier. It has to be unique inside its container. It is even better to name it uniquely inside the file.

- Visibility indicates the visibility (public or private) if the Enumeration is declared inside a Module. If it is declared in a Model Declaration, this information is useless.

Enumeration Value

It corresponds to an unnamed constant value whose type is an enumerated type

Children: none

Basic

- Type Value indicates the name of the enumerated type if any. A list of enumerated type containing in the scope is proposed.

- Value indicates the value used inside the enumerated type. No need to prefix the value with a '#' character.

Extraction

It corresponds to the extraction operator. A value is returned each time the Condition is true and there is a value on the Input Port.

Children

- One Input Port already created to connected the Signal Expression whose value has to be extracted each time the Condition is true.

Basic

- Name: the name of the operator. It is used to identify it, so it is better if it has a unique name.

History

It corresponds to the History state of an Automaton or of an And State. When a transition leads to such a state, it means that the container state is not reinitialized and re-executes its last state.

Children: none

If Then Else

It corresponds to the synchronous condition. It is an expression on signals of same clock.

Children:

- Two Input Ports already created. The first one has to be connected to the then Signal Expression, and the second to the else Signal Expression. Both expressions have to be of the same type.

else

then
Basic

Name: the name of the operator. It is used to identify it, so it is better if it has a unique name.

Index

It corresponds to the definition of an index. An index is a vector of integers whose size is equal to $(To - From)/Step$. It is used by Iterate model object.

Children: none

Basic

Comment: the COMMENT pragma attached to this identifier.

● From: a Signal Expression which constitutes the starting value of the Index.

● Name: the name of the Index which is used as its identifier. It has to be unique inside its container. It is even better to name it uniquely inside the file.

● Step: an integer Constant Expression different from 0. If the value is omitted, it is equal to 1.

● To: a Signal Expression which constitutes the ending limit of the Index.

Input

It corresponds to the declaration of an input signal in a Model Declaration. Because it represents an input of the declaration of a Model, it cannot be the target of a Dataflow Connection (only an Instance of the Input can be the target of a Dataflow Connection).

Children: none

Basic

Array Dimensions indicates the dimensions of the Input, if it is an array. If it is a multi-dimensional array, specify one dimension per line. A dimension is a constant expression: Constant Value, Parameter, an integer positive number...

● Comment: the COMMENT pragma attached to this identifier.

● Initial Value initialize the value of the Input.

● Name: the name of the Input which is used as its identifier. It has to be unique inside its container. It is even better to name it uniquely inside the file.

● Type: it corresponds to one of the Intrinsic Primitive Type or to one of the type declared. To access to a type declared in the file, the Input has to be in the scope of this declaration.

Input Instance

It corresponds to the instance of an Input. Inside a Model Instance, it refers to one of the Input declared in the instantiated Model Declaration. To obtain Input Instance model object, refer to the Model Instance description.

Children: none
Input Port

It corresponds to a port of a Signal Operator. By default, such port is not typed, but according to the operator containing the port, it is typed. Each Input Port has to be connected.

Children: none

Iterate

It corresponds to an iteration of processes. It is mainly used to apply the same behavior on arrays.

Children

● Input Port: this operator is as a multiple inputs operator, this means that you can add as many Input Ports as Indexes or integer array you need to connect. The ports are ordered.

● Iteration Init: this model object already created is used to specify, if any, how to initialize the iteration. When you try to delete this object, it is automatically rebuilt, but it will be empty.

● Any of the children that can be in a process: it means all model objects except the following list: And State, Input, Model Declaration, Output, Parameter, Pragma, State, Strong Transition, and Weak Transition.

Basic

● Comment: the COMMENT pragma attached to this identifier.

● Name: the name of the Iterate which is used as its identifier. It has to be unique inside its container. It is even better to name it uniquely inside the file.

Iteration Init

It corresponds to the area in which the initialization of an iteration of processes have to be made.

Children

● Any of the children that can be in a process: it means all model objects except the following list: And State, Input, Model Declaration, Output, Parameter, Pragma, State, Strong Transition, and Weak Transition.

Iterator

It corresponds to the iterator index of a C-for loop. It has to be used to refer the current number of loop of the Basic Iterate block. An Iterator can be referenced by a Constant Ref element.

Children: none

Basic

● Comment: the COMMENT pragma attached to this identifier.

● Name: the name of the Iterator index, which is used as its identifier. It has to be unique inside its container. It is even better to name it uniquely inside the file.

Literal

It corresponds to an unnamed constant value.

Children: none

Basic

● Value indicates the value of the literal. The literal can be either a boolean, or an integer, or a real, or a string, or a character value. If the literal is a string, do not
Local
It corresponds to the declaration of a local signal. This signal can be used at its declaration level and in all sub-levels.

- **Array Dimensions**: indicates the dimensions of the Local signal, if it is an array. If it is a multi-dimensional array, specify one dimension per line. A dimension is a constant expression: Constant Value, Parameter, an integer positive number...
- **Comment**: the COMMENT pragma attached to this identifier.
- **Initial Value**: initialize the value of the Local signal.
- **Name**: the name of the Local signal which is used as its identifier. It has to be unique inside its container. It is even better to name it uniquely inside the file.
- **Type**: it corresponds to one of the Intrinsic Primitive Type or to one of the type declared. To access to a type declared in the file, the Local signal has to be in the scope of this declaration.
- **Status**: indicates if the signal is a normal signal, a shared signal, or a state variable. A state variable is a typed sequence the elements of which are present as frequently as necessary. It keeps its previous value as long as a new one is defined. A shared signal is a signal whose value is partially defined at different place.

Merge
It corresponds to the operator that merge different flows of data. The flows are ordered according to the order of the Input Port to which they are connected. If there is a value on the first flow, it will be taken, else we check the second, and so on among the different flows.

- **Input Port**: this operator is a multiple inputs operator, this means that you can add as many Input Ports as Signal Expressions you need (at least 2) to connect. The ports are ordered.

Model Declaration
It corresponds to the declaration of a SIGNAL component with its Input/Output Signals and its input constant Parameter. It is only a declaration of a component. It has to be instantiated (Model Instance) to be used and connected to the rest of a system. It constitutes one of the Root Model, but it can also be declared locally in another Model Declaration or in a Module.

- **Input, Output, and Parameter**: are added to specify the interface of this component.
- **Specifications (already added)**: is used to specify the clock relations and the dependences between input and output signals.
- **Any of the children that can be in a process**: it means all model objects except those concerning the mode automaton: And State, State, Strong Transition, and Weak Transition.
- Transition.
- Basic
  - Comment: the COMMENT pragma attached to this identifier.
  - Name: the name of the Model Declaration which is used as its identifier. It has to be unique inside its container. It is even better to name it uniquely inside the file.
  - Visibility indicates the visibility (public or private) if the Model Declaration is declared inside a Module. If it is declared in a Model Declaration, this information is useless.

- Expert
  - Model Type: this attribute is of enumerated type whose values are action, function, node, and process. By default, the value of this attribute is process. For more information, consult the Signal v4 reference manual.
  - Process Class: this attribute is of enumerated type whose values are safe, deterministic, and unsafe. By default, the value of this attribute is unsafe. For more information, consult the Signal v4 reference manual.
  - Type indicates the Model Type of the Model Declaration if it is typed. Typing a Model Declaration by a Model Type is the means to reuse the same interface (Input/Output Signals and constant Parameters) for several Model Declarations. Thus, you have not to specify the interface of your Model Declaration, it is automatically specified by the Model Type.

- External Code
  - CCode: It is specific to code generation. It is a "parameterized" string representing a piece of C code. Each call of the model is translated by this string in the generated code, after substitution of the encoded parameters by the corresponding signals in the considered call. The following encoded parameters may be used in the string:
    - &p\_j (where j is a constant integer value) represents the jth parameter of the call;
    - &i\_j (where j is a constant integer value) represents the jth input signal of the call;
    - &o\_j (where j is a constant integer value) represents the jth output signal of the call;
    - &t&x\_j (where x is either p, i, or o, and j is a constant integer value) represents the type of the jth parameter, or input signal, or output signal of the call;
    - &n represents the name of the model.
  - Cpp Code: The same as CCode, but for the C++ generation.
  - Java Code: The same as CCode, but for the Java generation.

- Pragmas
  - Compilation Directive: this attribute is of enumerated type whose values are NONE, unexpanded, separate, Black Box, Grey Box, Delay Cluster, and Delay Cluster. By default, the value of this attribute is NONE. For more information, consult the list of Polychrony pragmas in the Signal v4 reference manual.
  - Is Main indicates if the Model Declaration is an entry point of a Module (used only when the Model Declaration is a child of a Module).
  - Is Sigali Process indicates if the current Model Declaration is a specific process for the Sigali model-checker tool.
  - Processor Type: string representing a name, for example, "DSP", that should be the name of a file DSP.LIB containing a module that defines the cost of each operator by particular models. When profiling (performance evaluation) is required on a given program implemented on some processor represented as a model with this attribute set, a morphism of this program is applied, that defines a new program representing

© Copyright IRISA/INRIA Rennes – ESPRESSO – 2007-2010

22
cost evaluation of the original program. The image of the original program by this morphism uses the library designated by the pragma to interpret the cost evaluation operators.

- Run On: a constant integer value i. When a partitioning based on the use of this pragma is applied on an application, the application is partitioned according to the n different values of the pragma so as to obtain n sub-models. The tree of clocks and the interface of these sub-models may be completed in such a way that they represent endochronous processes.

Model Instance

It corresponds to the instantiation of a SIGNAL component. To use it, specify the Referred Interface attribute, right-click on the Model Instance Node and select «Load Model Instance» action. This action creates the Input Instances, Output Instances, and Parameters Instances corresponding to those of the Referred Interface.

- Children
  - Input, Output, and Parameter Instances are automatically added when the Referred Interface is set and the «Load Model Instance Inputs/Outputs» action is called.

Basic

- Comment: the COMMENT pragma attached to this identifier.
- Name: the name of the Model Instance which is used as its identifier. It has to be unique inside its container. It is even better to name it uniquely inside the file.

Instantiation

- Referred Interface: refers to a Model Declaration or a Model Type to instantiate.
- Referred Parameter: for generic purpose, a Model Declaration can be passed as parameters. Thus, the Referred Interface has to be set with a Model Type, and the Referred Parameter will indicate the instantiated Model Declaration.

Model Ref

It allows to refer to a Model Declaration declared at the upper hierarchic level (only useful to connect a Model Declaration to a Parameter Instance).

- Children: none

Basic

- Model: points to the referring Model Declaration.

Model Type

It corresponds to the declaration of a specific type allowing to type a Model Declaration. As for a Model Declaration, an interface (Input, Output, Parameter, and a Specification area) has to be specified.

- Children
  - Input, Output, and Parameter are added to specify the interface of this component.
  - Specifications (already added) is used to specify the clock relations and the dependences between input and output signals.

Basic

- Comment: the COMMENT pragma attached to this identifier.
- Name: the name of the Model Type which is used as its identifier. It has to be unique.
Visibility indicates the visibility (public or private) if the Model Type is declared inside a Module. If it is declared in a Model Declaration, this information is useless.

- **Model Type:**
  - This attribute is of enumerated type whose values are `action`, `function`, `node`, and `process`. By default, the value of this attribute is `process`. For more information, consult the Signal v4 reference manual.

- **Process Class:**
  - This attribute is of enumerated type whose values are `safe`, `deterministic`, and `unsafe`. By default, the value of this attribute is `unsafe`. For more information, consult the Signal v4 reference manual.

- **Type** indicates the Model Type referenced by the current one.

- **Module** It corresponds to a library of types, components, and constant values.

- **Children**
  - **Model Declarations:** one can declared different Model Declarations. Some of them can be private (only usable by the other Model Declarations of the Module) or public (that can be imported by external Model Declarations that specify this Module in the Use Module model object). If one (or several) of the Model Declarations has its `Is Main` set to true, it becomes an entry execution point for this Module.
  - **Type (Enumeration, Model Type, Substitution Type, or Tuple Type)** can also be declared public or private.
  - **Constant Values** can also be declared public or private.
  - **Use Module:** indicates the list of other Modules needed by this one.

- **Basic**
  - **Comment:** the COMMENT pragma attached to this identifier.
  - **Name:** the name of the Module which is used as its identifier. It has to be unique inside its container. It is even better to name it uniquely inside the file.

- **Not**
  - It corresponds to the logical Not operator.

- **Children**
  - **One Input Port (already created):** used to connect a Boolean Expression.
Basic

Expression: the arithmetic expression in textual form.

Name: the name of the operator. It is used to identify it, so it is better if it has a unique name.

Or
It corresponds to the logical Or operator.

Children:

Input Port: this operator is a multiple inputs operator, this means that you can add as many Input Ports as Signal Expressions you need (at least 2) to connect. The ports are ordered.

Basic

Name: the name of the operator. It is used to identify it, so it is better if it has a unique name.

Output
It corresponds to the declaration of an output signal in a Model Declaration.

Children: none

Basic

Array Dimensions indicates the dimensions of the Output, if it is an array. If it is a multi-dimensional array, specify one dimension per line. A dimension is a constant expression: Constant Value, Parameter, an integer positive number...

Comment: the COMMENT pragma attached to this identifier.

Initial Value initialize the value of the Output.

Name: the name of the Output which is used as its identifier. It has to be unique inside its container. It is even better to name it uniquely inside the file.

Type: it corresponds to one of the Intrinsic Primitive Type or to one of the type declared. To access to a type declared in the file, the Output has to be in the scope of this declaration.

Output Instance
It corresponds to the instance of an Output. Inside a Model Instance, it refers to one of the Output declared in the instantiated Model Declaration. To obtain Output Instance model object, refer to the Model Instance description.

Children: none

Basic

Comment: the COMMENT pragma attached to this identifier.

Name: the name of the Output Instance which is used as its identifier. It has to be unique inside its container. It is even better to name it uniquely inside the file.

Output Port
It corresponds to an output port of a Cartesian Product (it is the only Signal Operator with Output Ports). Each Output Port has to be connected to a Signal (Input Instance, Local, Output), or to a Signal Reference.

Children: none
Parameter
It corresponds to the declaration of a constant parameter in a Model Declaration.

- Children: none
- Basic
  - Array Dimensions indicates the dimensions of the Parameter, if it is an array. If it is a multi-dimensional array, specify one dimension per line. A dimension is a constant expression: Constant Value, Parameter, an integer positive number...
  - Comment: the COMMENT pragma attached to this identifier.
  - Name: the name of the Parameter which is used as its identifier. It has to be unique inside its container. It is even better to name it uniquely inside the file.
  - Type: it corresponds to one of the Intrinsic Primitive Type, to one of the type declared, or it can be of type type.

Parameter Instance
It corresponds to the instance of a Parameter. Inside a Model Instance, it refers to one of the Parameter declared in the instantiated Model Declaration. To obtain Parameter Instance model object, refer to the Model Instance description.

- Children: none
- Basic
  - Comment: the COMMENT pragma attached to this identifier.
  - Name: the name of the Parameter Instance which is used as its identifier. It has to be unique inside its container. It is even better to name it uniquely inside the file.

Pragma
It corresponds to the definition of a pragma whose role is to associate specific informations with the objects of a Model.

- Children: none
- Basic
  - Expression: a string representing the information to associate with the target objects.
  - Name: the name of the operator. It is used to identify it, so it is better if it has a unique name.
  -Pragma: a string which represents the kind of the pragma
  - Target: a list of identifiers on which this pragma is applied.

Repetition Operator
It corresponds to the repetition operator, which is a simple form of iterative enumeration, which allows the finite repetition of a value. The result of this operator is an array with several times the value connected to the first Input Port. The number of repetitions is represented by the second Input Port.

- Children
  - Two Input Ports already created. The first one takes an expression used to fill the array and the second takes the number of repetitions, i.e. the size of the built array.

© Copyright IRISA/INRIA Rennes – ESPRESSO – 2007-2010
The expression connected to the second Input Port have to represent a strictly positive integer value.

Basic
- Name: the name of the operator. It is used to identify it, so it is better if it has a unique name.

Sequential Definition
- It corresponds to the sequential definition operator, which is used mainly for the redefinition of elements of arrays. For an example with 2 Input Ports, the result will be an array which takes the value of the expression connected to the second Input Port at each point at which it is defined, and the value of the expression connected to the first Input Port elsewhere. In the general case, both expressions value are arrays with the same number of dimensions.

Children:
- Input Port: this operator is a multiple inputs operator, this means that you can add as many Input Ports as Signal Expressions you need (at least 2) to connect. The ports are ordered.

Basic
- Name: the name of the operator. It is used to identify it, so it is better if it has a unique name.

Signal Ref
- It corresponds to the use of a Signal (Input, Output, Local, Input Instance or Output Instance) at another hierarchical level than these where the Signal is declared.

Children: none

Basic
- Signal: points to the referring Signal.

Specifications
- It corresponds to the area to specify some properties. It uses a process expression that can make reference (through Constant Ref, or Signal Ref) to the Parameters and Input and Output signals of the Model. Any other identifier used in this expression is that of a local object (signal, process model, etc.), that must have a declaration in this expression. This area is used in Model Declaration and Model Type model objects for this reason. It is also used in the Tuple Type declaration to specify some properties between different signals, if the Tuple Type is a bundle.

Children
- Any of the children that can be in a process: it means all model objects except the following list: And State, Input, Iteration Init, Model Declaration, Output, Parameter,Pragma, Specifications, State, Strong Transition, and Weak Transition.

State
- It corresponds to a leaf-state of an Automaton. It contains directly the specification of the mode.

© Copyright IRISA/INRIA Rennes – ESPRESSO – 2007-2010
Children

● Any of the children that can be in a process: it means all model objects except the following list: And State, Input, Iteration Init, Model Declaration, Output, Parameter,Pragma, Specifications, State, Strong Transition, and Weak Transition.

Basic

● Comment: the COMMENT pragma attached to this identifier.

● Name: the name of the state which is used as its identifier. It has to be unique inside its container. It is even better to name it uniquely inside the file.

Strong Transition

It corresponds to a transition of an Automaton. A Strong Transition is evaluated, for the current instant, before the execution of its source state. If the guard is true, the mode of the Automaton for the current instant will be the target state. In a specific Automaton, only one Strong Transition can be taken during an instant.

Children: none

Basic

● Guard is a textual boolean expression to express when to go from the source state to the target state.

● Name: the name of the model object. It is used to identify it, so it is better if it has a unique name.

● Priority is an integer value which indicates, for states with several out-going Strong Transitions, the order of their evaluation.

Source-Target

● Dst: the target of a Strong Transition is a sub-state (And State, Automaton, or State) of the Automaton which belongs this transition, or the History of one of them.

● Src: the source of a Strong Transition is a sub-state (And State, Automaton, or State) of the Automaton which belongs this transition.

Sub Process

It corresponds to a sub part of a component without any specific Input/Output signals. It can also be used to specify the different case of the Switch operator. One can also specify some clock constraints/relations (or dependences) with a Sub Process: this means that all signals defined in the Sub Process will be related to these constraints/relations.

Children

● Any of the children that can be in a process: it means all model objects except the following list: And State, Input, Iteration Init, Model Declaration, Output, Parameter,Pragma, Specifications, State, Strong Transition, and Weak Transition.

Basic

● Comment: the COMMENT pragma attached to this identifier.

● Name: the name of the Sub Process which is used as its identifier. It has to be unique inside its container. It is even better to name it uniquely inside the file.

Substitution Type

It corresponds to a generic type that can refer another one.
● Array Dimensions indicates the dimensions of the Substitution Type, if it is an array type. If it is a multi-dimensional array type, specify one dimension per line. A dimension is a constant expression: Constant Value, Parameter, an integer positive number...

● Comment: the COMMENT pragma attached to this identifier.

● Is External indicates if the referenced type is defined outside the context of the Model (for example, in a C library).

● Name: the name of the Substitution Type which is used as its identifier. It has to be unique inside its container. It is even better to name it uniquely inside the file.

● Type: it corresponds to one of the Intrinsic Primitive Type or to one of the type declared. To access to a type declared in the file, the Constant Value has to be in the scope of this declaration.

● Visibility indicates the visibility (public or private) if the Substitution Type is declared inside a Module. If it is declared in a Model Declaration, this information is useless.

Switch
It corresponds to a switch operator. A signal is tested, and the different cases are expressed in Sub Processes linked to the Switch by a Case Connection.

Children: none

Basic
● Name: the name of the operator. It is used to identify it, so it is better if it has a unique name.

● Signal: points to the tested Signal.

● Src Field: if the tested Signal uses a Tuple Type or an array type, this attribute is the way to access to the signal field.

Not implemented by the compiler yet.

Transposition
It corresponds to the matrix transposition operator.

Children
● One Input Port (already created) connected to the matrix expressions to transpose.

Basic
● Name: the name of the operator. It is used to identify it, so it is better if it has a unique name.

Tuple Operator
It corresponds to the tuple operator, which allows to create a tuple with unnamed fields (opposite to a Signal declare with a Tuple Type).

Children:
● Input Port: this operator is a multiple inputs operator, this means that you can add as many Input Ports as Signal Expressions you need (at least 2) to connect. The ports are ordered.

Basic
● Name: the name of the operator. It is used to identify it, so it is better if it has a unique name.

Not implemented by the compiler yet.
Tuple Type
It corresponds to the declaration of structured types, called also in a generic way tuple types with named fields. There are two categories of tuple types: polychronous, and monochronous. An object typed by a polychronous tuple is in fact a gathering of objects.

In this way, a polychronous tuple of signals is not a signal (it has no clock). At the opposite, an object declared of type monochronous tuple can be a signal: it has a clock (all its named fields are synchronized). Only monochronous tuple can be used as the the type of the elements of an array. A tuple type is defined by a list of typed and named fields; in addition, clock properties can be specified on the fields of a tuple.

Children
● Local signals are used to represent the named fields inside the tuple types.
● The Specifications area is used to precise the clock properties between the different fields when the Kind attribute is a polychronous tuple. For monochronous tuple, the Specifications area must be empty.

Basic
● Array Dimensions indicates the dimensions of the Tuple Type, if it is an array type. If it is a multi-dimensional array, specify one dimension per line. A dimension is a constant expression: Constant Value, Parameter, an integer positive number...
● Comment: the COMMENT pragma attached to this identifier.
● Kind: this attribute is of enumerated type whose values are bundle (polychronous tuple), and struct (monochronous tuple). By default, the value of this attribute is struct.
● Name: the name of the Tuple Type which is used as its identifier. It has to be unique inside its container. It is even better to name it uniquely inside the file.
● Visibility indicates the visibility (public or private) if the Tuple Type is declared inside a Module. If it is declared in a Model Declaration, this information is useless.

Unary Minus
It corresponds to the unary negation arithmetic operator.

Children
● One Input Port (already created) connected to a numerical expression.

Basic
● Name: the name of the operator. It is used to identify it, so it is better if it has a unique name.

Use Module
It corresponds to the operator to import Modules.

Children: none

Basic
● Modules: the ordered list of imported Modules. To import a Module, you have to add it manually (for the moment) to the Outline of your project, by right-clicking on the root of the Outline and by selecting «Load Resource». Select then the SME file.
Variable

It corresponds to the variable operator, which allows to use a signal at any clock defined by the context. The result of this operator is a Signal whose value is the value of the Signal Expression connected to the Input Port, when this expression is present, or the last value of the expression otherwise. The initial value is used when the Signal Expression has not been present yet.

Children

● One Input Port (already created) connected to a Signal Expression.

Basic

● Initial Value initialize the value of the operator before it receives the first value of the Signal Expression.

● Name: the name of the operator. It is used to identify it, so it is better if it has a unique name.

Weak Transition

It corresponds to a transition of an Automaton. A Weak Transition is evaluated, for the current instant, after the execution of its source state. If the guard is true, the mode of the Automaton for the next instant will be the target state.

Children: none

Basic

● Guard is a textual boolean expression to express when to go from the source state to the target state.

● Name: the name of the model object. It is used to identify it, so it is better if it has a unique name.

● Priority is an integer value which indicates, for states with several out-going Weak Transitions, the order of their evaluation.

Source-Target

● Dst: the target of a Weak Transition is a sub-state (And State, Automaton, or State) of the Automaton which belongs this transition, or the History of one of them.

● Src: the source of a Weak Transition is a sub-state (And State, Automaton, or State) of the Automaton which belongs this transition.

Window

It corresponds to the sliding window operator, which returns an array composed by the Window Size-th last values of the expression connected to the Input Port.

Children

● One Input Port already created to connected the Signal Expression.

Basic

● Initial Value initialize the value for the (Window Size-1)-th first execution of the operators. This means that this attribute is an array whose size (the first dimension of the array) is equal to (Window Size-1).

● Name: the name of the operator. It is used to identify it, so it is better if it has a unique name.

● Window Size is an integer constant expression whose value is greater than or equal to.
1. If it is equal to 1, the Initial Value is useless.

Xor

It corresponds to the logical Xor operator.

Children:

- Input Port: this operator is a multiple inputs operator, this means that you can add as many Input Ports as Signal Expressions you need (at least 2) to connect. The ports are ordered.

Keywords of the language

The graphical modeler plug-in

- Interface Definition Diagram,
- Data flow Diagram,
- Clock Relations and Dependences Diagram,
- Library Diagram,
- Mode Automaton Diagram,
- Tuple Type Diagram.

Each of these diagrams represents a specific aspect in the modeling of a SME Model and will be detailed in the following. Before this, we first explain how to create a new project and a new diagram.

Creation of a new SME diagram from a Template

New-> Other... Polychrony->SME Diagram.

Remark Topcased Modeling
Once you have selected the SME diagram, the SME wizard is opened. Thus, you have to choose the name of the diagram and the kind of diagram you want to display.

Remark:
Mode Automaton Diagram       Tuple Type Diagram

Creation of a new SME diagram from an existing SME file model

New->SME Diagram
When the SME Diagram wizard is opened, you have only to choose the kind of root diagram (see next part for a description if each kind of diagrams). If the diagram must be initialized directly, check the corresponding check box. You can also drag the different elements from the Outline to position them more relevantly.

Diagram Accessibility and Aspects
Interface Definition Diagram

This diagram is used to visualize/specify the interface of a Signal component (basically a process) or those of the declaration of a type used to type a component. The root of this diagram is a Model Declaration object, if you create it through the SME wizard, and can be either a Model Declaration or a Model Type otherwise. This diagram is used to specify the Input/Output signals and the constant Parameter of the interface of a component, and also some pragmas.

Each model elements that can have an Interface Definition Diagram contains a Specification model, whose role is to specify the clock relation between the input/output signals. If you want to modify or display it, drag it from the Outline view. This model is mainly used in component abstractions for separated compilation purposes.

Add Diagram

Goto Aspect

Remark:

Interface Definition Diagram
To parametrize each of these elements, right-click on any graphical object and select the Property View. For more information, refer to the Parametrization of model objects section (select the Advanced tab, to view the attribute and references of each model object).

Data flow Diagram

- **Containers:**
  - Input signal
  - Constant input parameter
  - Output signal

- **Typologies:**
  - Basic Iteration is used to express an iteration as a C-for loop. To use it, give the name of its iterator and the value of the upper bound. To specify the initialization part of the Basic Iteration, right-click on the Basic Iteration and select the Show the Iteration Init part action, which display the Data flow Diagram for it. Finally, to specify the process on which the Iteration iterates, double-click on it to open a Data flow Diagram.

- **Typologies:**
  - Iteration is used to express iteration of processes. To use it, connect at least an index to its Input Port. It is also possible to iterate on several indexes; for this purpose, right-click on the Iteration, and select the Add a New Port action to add a new Input Port to connect another index. For the initialization part and the iterated process, it is the same as for the Basic Iteration Block.

- **Typologies:**
  - A Mode Automaton can be added. For more information on it, consult the Mode Automaton Diagram section.

- **Typologies:**
  - Local Model Declarations (Action, Function, Node, and Process) can also be declared inside this diagram, and Model reference can refer to the declaration of a Model Declaration declared at another level.

- **Typologies:**
  - To instantiate a Model Declaration, use a Model Instance object. To use it, specify the Referred Interface attribute, right-click on the Model Instance, and select «Load Model».

---

Copyright IRISA/INRIA Rennes – ESPRESSO – 2007-2010
• **Identifiers:**

  - Constant reference
  - Constant value
  - Index
  - Literal
  - Local signal
  - Signal reference

• **Operators:**

  Add a New Port
• **Links:**
  - Case connector is used to connect a switch operator to a Sub Process (or an Iteration).
  - Condition connector is used to connect a Boolean Expression or a Signal to a conditioned expression, which can be either an Extraction operator, or an If-Then-Else operator, or a Memorization operator, or an Assertion.
  - A Constant affectation is used to connect a constant expression to a Parameter Instance contained by a Model Instance.
  - Finally a Dataflow Connector is used to connect any Signal expression that returns a result to a signal (or to the Input Port of another operator). It corresponds to the definition (or partial definition) operator of the SIGNAL language.

• **Miscellaneous:** This section contains the way to specify Assertion and to import Modules. An assertion can be defined by specifying its expression attribute (right-click on the Assertion, and select the *Edit Composite expression* action) or by connecting a Condition link to it. To import a Module, right-click in the Outline view, select the *Load Resource* action, and then select the same file containing the Module. Finally, you have to add this Module in the list of Modules attribute of the Use Module model object.

To parametrize each of these elements, right-click on any graphical object and select the *Property View*. For more information, refer to the *Parametrization of model objects* section (select the *Advanced* tab, to view the attribute and references of each model object).

**Clock Relations and Dependences Diagram**
and in a Data flow Diagram.
The list of clock identifiers are any kind of Signal (Input, Output, Local, Input Instance, Output Instance), a Signal Ref, a Model Instance, a Sub Process, Iterate, and Automaton model objects. If such an identifier is contained by the root element of a Clock Relation Diagram, drag it from the Outline view to the diagram.

As in the Data flow Diagram, you can declare Locals signals or refer to signal declared at a higher level. The difference with the previous diagram is on the manipulated operators. In a Clock Relations and Dependences Diagram, there are only clock operators:

- Clock Constraint Operator: Clock Synchronization, Clock Exclusion, and Clock Identity.
- Clock Relation Operator: Clock Union, Clock Intersection, and Clock Complementary.
- Clock Speed Operator: Clock Slower, and Clock Faster.

Since version 0.15.0, the Clock Constraint Operators and the Clock Speed Operators has been extended to be available in assertion block. They are represented here as special Clock Constraint Assertion and Clock Speed Assertion and can be used respectively as Clock Constraint Operators and Clock Speed Operators.

Among these operators, the Clock Relation Operators and the Clock Speed Operators have Input Ports. It can have as many Input Ports as needed. To add new Input Port, right-click on the graphical representation of the operator, and select the Add a New Port action.

The Clock Relation link is used to connect the identifiers to the operators. A Clock Constraint Operator cannot be the source of such a connection and it can receive as many connection as needed as target. A Clock Relation operator can only be the source of such connection and its Input Ports the target of such connection (one per Input Port). A Clock Speed Operator can be either the source or the target of such connection.
Remark:

- A Clock Relation link can be used between two clocked identifiers correspond to a synchronization of the clock of both identifiers.
- The Null Clock is used as a constant to express some clock relations.

Dependences are the means to express the scheduling of different parts of the component. Using a Dependence relation between two clock identifiers means that the one at the source of the relation has to be computed before the one at the target. The Dependence operator is the way to express multiple sources and multiple targets in one relation. It is also possible with the Dependence Operator to express conditioned scheduling. For this purpose, use a Condition link from a boolean signal to the Dependence Operator.

To parametrize each of these elements, right-click on any graphical object, and select the Property View. For more information, refer to the Parametrization of model objects section (select the Advanced tab, to view the attribute and references of each model object).

43
The compilation scenarios plug-in

The goal of this plug-in is to allow the creation of compilation scenarios for Polychrony model. A compilation scenario is composed of different kinds of functionalities and of generators. A functionality modifies the internal representation of the program whereas a generator translates this representation into a specific external format. The meta-model of this plug-in is shown on the next picture.

Functionalities

- Re-timing: It performs a shift register transformation. It rewrites synchronous function \( f \) such that \( Y := f(X_1 \oplus m_1 \text{ init } V_1, ..., X_n \oplus m_n \text{ init } V_m) \) into \( Y := y' \oplus j \text{ init } f(V_1', ..., V_m') \) and \( y' := f(X_1 \oplus m_1' \text{ init } V_1'', ..., X_m \oplus m_m' \text{ init } V_m'') \).

- Booleans to events: It rewrites boolean expressions of under-sampling for logical and relational operators. The goal is to prove synchronization constraints of the system.
  - the rewriting of the boolean expressions referenced in an extraction (\( \text{when } E \) when \( E \) is not a "free" condition and not declared as an assumption. For example, the expression \( \text{when } (A \text{ and } B) \) is equal to the clock intersection of \( \text{when } (A) \) and \( \text{when } (B) \). So, "classical boolean rules" completed with some specific rules induced by the extraction and merging Signal operators are applied to the system.
  - the rewriting of the boolean expressions referenced in the extraction (\( \text{when } E \) when \( E \) is assumed to be an assertion: the expression \( \text{assert}(E) \) specifies that \( E \) is always true when \( T \) for example).
Generators

- Signal Textual (SIG): it translates the internal representation of the specification into a textual Signal file (.sig file).
- Signal Textual (LIS): it translates the internal representation of the specification into a textual Signal file (.sig file), after the graph creation. The errors will be written on the file.
- Signal Textual (TRA): it translates the internal representation of the specification into a textual Signal file (.sig file), after the clock calculus phase.
- Signal Model (Sme): it translates the internal representation of the specification into a XMI Model Signal file (.sme file). This model file is conformed to the SME meta-model.
- Signal Abstraction: it translates the abstraction of the internal representation into a textual Signal file (.sig file).
- Sigali: it translates the internal representation of the specification into a textual Sigali file (.z3z file). This file is then used by Sigali to prove dynamical properties.
- C ANSI: it translates the internal representation of the specification into a textual C ANSI files (.c and .h files). These files are used to simulate the Signal specification. It is applied to a graph which must be a sbDC+ one. The graph is with or without clusters.
C++: it translates the internal representation of the specification into a textual C++ files (.cpp and .h files). These files are used to simulate the Signal specification. It is applied to a graph which must be a sbDC+ one. The graph is with or without clusters.

Java: it translates the internal representation of the specification into a textual Java files (.java files). These files are used to simulate the Signal specification. It is applied to a graph which must be a sbDC+ one. The graph is with or without clusters.

Profiling: it produces the morphism of the internal representation according to the definitions assigned of the Signal operators given in the "ht" table into a textual Signal file (.sig file).

Lustre: it translates the internal representation of the specification into a textual Lustre file (.lus file).

Syndex: it translates the internal representation of the specification into a textual SynDEx file (.sdx file) for code distribution.

Reflexive editor

The reflexive editor has been automatically generated from the compilation scenario meta-model. To create a new compilation scenario file (.ssc), right-click on your project and select New->Other... and then select the following model: Polychrony->SME Compilation Model.

However, there are some constraints to create a compilation scenario, because some functionalities/generators can only be applied after others, so an interactive view (described in next part) has been created to help user to create such scenario.

SME Scenario View

The SME Scenario View (see following picture) constitutes a way to describe a compilation scenario with some assistance. Each functionality and generator is represented by a button and, according to the functionality or generator you activate, others become available or are disabled. Since version 0.5.0, a check box to enable/disable the display of all warnings has been added.

To access to this view, select Window-> Show View-> Other... Polychrony->SME Scenario
The Signal text editor

Since v0.18.0, the SME environment integrates a simple text editor to manipulate Signal Text files inside Eclipse. The current version provides only syntax highlighting for Signal keywords, for comments, and for constant value using primitive types (string, character, or numerical value).

To use this editor, you have only to double-click on the file with extension .SIG. Maybe the Signal Text editor is not selected by default, so, you have to right-click on the file and select Open With->Signal Text Editor.
The connection to the Polychrony services

How does the connection work?

1. First, the SME model is transformed into the abstract syntax tree (AST) representation inside the compiler. A SME model parser that makes this translation has been developed. At this step, the parser can report all errors concerning the well-formedness of the model and the parsing errors (for attributes that contain SIGNAL syntax).

2. Then, this AST representation is transformed into an internal graph structure. This step consists in resolving all references specified inside the AST, checking the type errors, and making explicit all implicit clock constraints and clock relations. This means that new signals, which do not exist in the source model, are created. The traceability consists in linking each new signal to the corresponding original AST object.

3. The third step consists in applying to this graph the different Polychrony services specified in the compilation scenario (clock resolution, code generation...). These operations also modify the graph obtained at the previous step.
Finally, by analyzing the graph obtained after these transformations, some errors can be reported in the graphical part. At this time, only type errors can be seen on the diagram. As we can see in the following picture, a little red symbol is written on the operator to let the user know that there is an error.

A Hashmap between the Polychrony native AST and the SME instances has been built, in order to associate the node of the native AST where the error message is written and the corresponding instance. For example, here, the "disagreement between types of operands" error is linked with the Addition operator.

Errors:
- **ERROR: disagreement between types of the operands
- **ERROR: disagreement between types of operands
Compiler configuration

The Signal compiler can be parameterized to specify the memory size used for its operations. To access these parameters, select the Polychrony section in the Preferences Window as shown in the following picture.

- The Polychrony library path.
  - fr.irisa.espresso.sme.polychrony.win32.win32.x86_<version>
  - fr.irisa.espresso.sme.polychrony.gtk.linux.x86_<version>
  - fr.irisa.espresso.sme.polychrony.carbon.macosx.x86_<version>
directory>/apex_arinc653/lib

- Maximum number of types.
- Memory size for the internal structure.
- Memory size for the string structure.

Applying Polychrony services

To call Polychrony services, right-click on the SME file on which you want to apply the service(s), and select Polychrony. You can choose to use a predefined scenario: in this case, select the Execute Predefined Scenarios option.
Seven actions are proposed:

- Generate C files from the selected SME model
- Generate C++ files from the selected SME model
- Generate Java files from the selected SME model
- Generate SIG file from the selected SME model
- Generate SIG (LIS) file from the selected SME model
- Generate SIG (TRA) file from the selected SME model
- Execute a compilation scenario on the model

The three first actions generate the executable code files respectively in C, C++, and Java languages from the SME model specifications. The next three actions generate a Signal textual file: a normal SIG file, a pretty printing of the tree internal structure or a Signal file generated during the transformation to the internal graph structure. The last option applies a compilation scenario on the SME model (see previous part). All these files are generated only in a directory named as the SME model file. They are only generated if all previous compilation steps are all successful.

It is also possible to call Polychrony services on SIG file. In the same manner as for the SME file, right click on the SIG file, and select Polychrony to obtain all actions proposed for the SME file and one action to generate a SME file from the SIG file in a directory named as the SIG file.

There are two new options that appeared in the 0.20.0 version of the plugin: the interactive compilation and the general compilation. Let's see the interactive compilation first: to be able to use it, choose the General Compilation menu in the Polychrony menu, and then click on Interactive Compilation.
A new window will pop up, with all the options available in the scenario editor. Each time you click on an option, the corresponding operation is realized in real-time. When you have finished, you can close this window by clicking on the **Quit** button.
Java

For the Java generation code, we take benefit of Eclipse which is originally a Java environment that provides several facilities to manage Java project. The call of the Java generation code creates (if all previous operations are executed without errors) a Java project containing the Polychrony Java libraries (SignalJavaStd.jar, and SignalGraphicalJavaStd.jar) and the Java source classes are generated in the src directory of the project. There may be some errors in the Java code if your SME model has constant parameters. The correction of these errors consists in replacing the UNDEF() calls by the value of the constant parameter.

To execute the simulation, you have only to right-click on the project (or on the Java class corresponding to the main) and select Run As->Java Application.
The example plug-in

Polychrony Examples-> Polychrony Examples

Counter

reset

reset val
Input and the output signals appear in the diagram. Now, you have only to drag and drop the operators from the palette.

- A local integer signal (called `counter`) is declared. It is defined by the previous value of the `val` output signal. To build such a relation, drag the delay operator from the palette and customize its attributes (Nb Instants to 1, Initial Value to 0), then connect its input port with a dataflow connection, whose source is the `val` output signal. Finally, connect the delay operator to the `counter` local signal with a dataflow connection.

- The `val` output signal is defined as 0 when the `reset` event is present and as `counter` + 1 otherwise. To build the first case, drag an Extraction operator from the palette and connect its input port to a literal (whose value is 0) with a dataflow connection and connect a condition link from the `reset` event to the Extraction operator and set its Condition Kind attribute to Present. To build the second case, drag an Addition operator from the palette (it is an arithmetic operator with its Operator attribute set to Addition). Connect its input port to `counter` and to a literal whose value is 1 (in any order here, because the Addition operator is a commutative one). Finally, connect the result of these two cases (the Extraction operator and the Addition one) to a Merging operator (dragged from the palette), and connect its input port (here in the relevant order) to both cases, and the Merging operator to the `val` output signal with dataflow connections.

Remark:
- In this example, the use of the local signal `counter` is not necessary, we could connect directly the delay operator to the input port of the Addition operator.
- We do not need any clock relations and dependences diagram here, because the clocks of each signal are set implicitly. Here `val` and `counter` have the same clock (linked through a delay operator), and the clock of `reset` is a subset of those of `val`.
Watchdog

The second example is the specification of a Watchdog process. This example is not more complicated as the previous one, but it shows the use of a Clock Relations and Dependences Diagram and some specific actions on some operators.

**Specification:**
- A process emits an `order` to be executed within some `delay`.
- When finished, a `finish` signal is made available.
- The Watchdog is designed to control this `delay`.
- It receives a copy of `order` and `finish` signals.
- It must emit an `alarm` whenever a job is not finished in time.
- If a new `order` occurs when previous one is not finished, the time counting restarts from zero.
- A `finish` signal out of delay, or not related to an `order`, will be ignored.

An `order` is supposed to be coded by an integer. The process receives also as other input the `finish` signal, which is an event. In order to count the time, synchronous languages do not use language-defined devices, like `seconds`, whose accuracy is not sufficient. The source of time is also an input signal called `tick`, of type `event`. The amount of time between two such time events is defined by the environment. The parameter `DELAY` is expressed as a number of `tick`.

As output, the process produces an `alarm` when the `DELAY` between `order` and `finish` is exceeded. This `alarm` is an integer corresponding to the `hour` (the number of `tick` since the beginning of execution) at which the `alarm` is sent.

The following pictures are screen shots of the Data flow Diagram of the Watchdog and of the Clock Relations and Dependences Diagram.

- ● The **Merging** operator has 4 Input Ports. As other operators, the Merging is an n-ary operators, so it is possible to add as many Input Port as needed. For this purpose, you have only to right-click on the Merging graphical element and to select the **Add new port** action.
- ● The **Condition** link has boolean expressions (and not a Signal) as source and true as Condition Kind (not present).
- ● In the diagram, there are different graphical element with the same name. In fact, there are two Constant Value declarations (`ZERO` and `ONE`), and two Constant Refs, which point to these declarations.

Add new port
Some signals, as `hour` and `cnt` (or `zcnt`), have a free clock, thus they have to be defined explicitly in a Clock Relations and Dependences Diagram (as shown on the following picture).

- In the textual specification, `hour` is defined as being the number of `tick` since the beginning of the execution, so `hour` and `tick` have to be synchronized (at each `tick`, `hour` must be incremented). To build such relation, drag the "Clock Synchronization" operator from the palette and connect Clock Relation link from `hour` and `tick` to this operator.

- According to the specification, the Local signal `cnt` is updated when an `order` or a `finish` signal is emitted, or is decremented at each `tick`. So, the clock of `cnt` is the union of the clocks of `order`, `finish`, and `tick`. To build such relation, drag a "Clock Union" operator (in fact Clock Relation operator with the Operator attribute set to Union) from the palette, and add a new Input Port (as with the Merging operator). Finally, connect `order`, `finish`, and `tick` to each Input Port of the "Clock Union" operator and the operator to `cnt` with Clock Relation links.

Remark:

Remark:
Remark

● If a state has several out-going transitions, do not forget to set different value for the Priority attribute of each one. The smallest value has the highest priority.

● The guard of a Strong Transition must not refer to signals whose value are computed inside a sub-state.
